Cultural Consumption and Intersectionality. Analysis of the Survey of Public Participation in the Arts

Description du sujet :

Cultural consumption refers to the goods, practices, and activities?such as attending concerts, visiting museums and galleries, reading, or engaging with the arts?through which individuals engage with cultural life. Cultural consumption inequalities have long fascinated social scientists, as the cultural goods, practices, and experiences people consume serve as key mechanisms through which social classes are maintained and individuals distinguish themselves from others while displaying their social position. But who consumes the "right" cultural products, and are inequalities in cultural consumption intersectional?

This StatApp project brings together two fundamental social science questions using high-quality data and cutting-edge statistical tools. Intersectionality provides an analytical framework for understanding how interlocking systems of oppression?such as racism, sexism, classism, and ableism?interact and mutually shape individuals' experiences of inequality and power dynamics. Rather than examining these factors in isolation, intersectionality recognizes that people's identities and experiences are shaped by the simultaneous operation of multiple systems of power and privilege.

Using data from the Survey of Public Participation in the Arts (SPPA) 2022, we will analyze whether the determinants of cultural consumption in the United States operate intersectionally. This analysis will employ random-effects models in a novel framework called "intersectional MAIHDA" (Multilevel Analysis of Individual Heterogeneity and Discriminatory Accuracy), a modeling approach that efficiently accommodates large numbers of interaction terms (age $\times$ gender $\times$ race $\times$ education $\times$ income $\times$ region...) in regression models.

While random-effects models are often neglected in econometrics courses (because, no one can deny it, fixed-effects models have important features and are easier to understand), in situations involving complex intersectional analyses, random effects models come in quite handy. The intersectional MAIHDA approach allows us to model hundreds of potential intersectional positions simultaneously while maintaining statistical power and interpretability.

Statistical software will be Stata or R, depending on the students' preferences.

At the end of this project, students will have:

- An advanced understanding of intersectional analysis methods and their application to cultural consumption research
- Expertise in intersectional MAIHDA modeling techniques, a cutting-edge approach for analyzing complex social stratification
- Comprehensive knowledge of the Survey of Public Participation in the Arts, a nationally representative dataset that provides unique insights into Americans' cultural behaviors and preferences
- Skills in analyzing cultural consumption patterns across multiple dimensions of social identity simultaneously

Données du sujet :

The Survey of Public Participation in the Arts (SPPA) is conducted by the U.S. Census Bureau for the National

Endowment for the Arts. The 2022 wave collected data from a nationally representative sample of approximately 13,000 U.S. adults, measuring their participation in various cultural activities including attendance at performing arts events, visits to museums and galleries, reading literature, and engagement with digital arts content. The survey includes detailed demographic information that enables intersectional analysis across multiple social categories.

The SPPA has been conducted periodically since 1982 and provides the most comprehensive data available on Americans' cultural participation patterns. Data and documentation are publicly available through the National Endowment for the Arts and the U.S. Census Bureau.

Modèles envisagés du sujet :

Intersectional MAIHDA (Multilevel Analysis of Individual Heterogeneity and Discriminatory Accuracy), a random-effects framework accommodating large numbers of interaction terms (age × gender × race × education × income × region...). Statistical software: Stata or R, depending on student preference.
